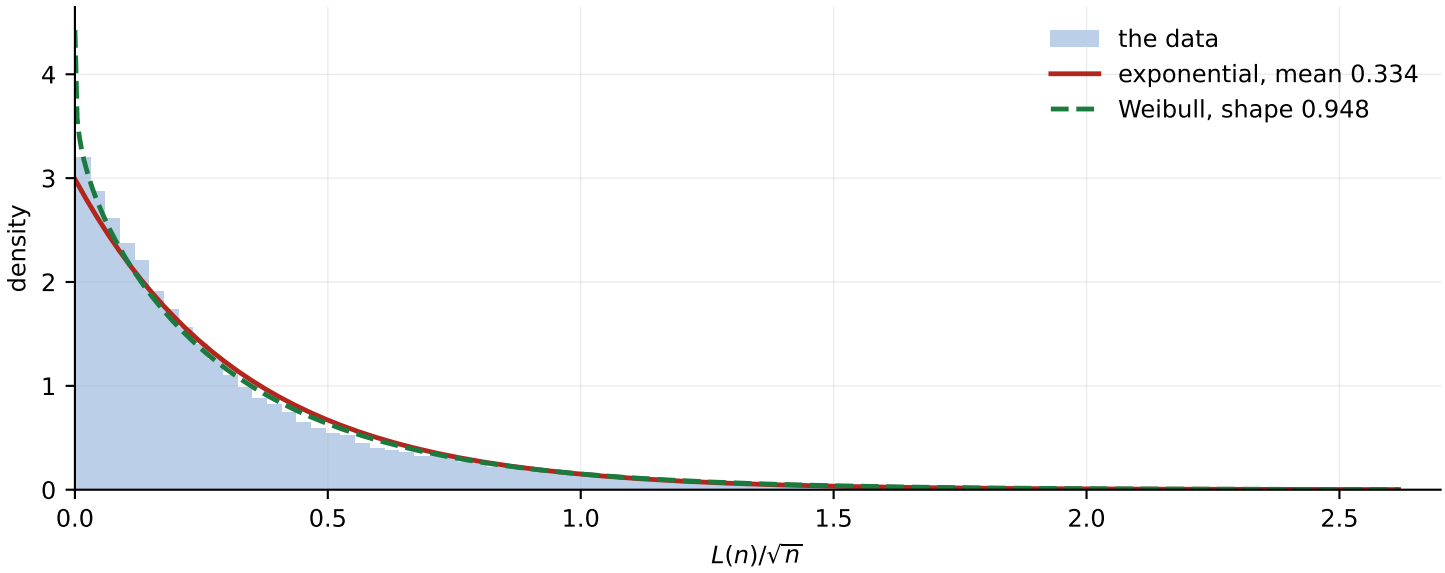
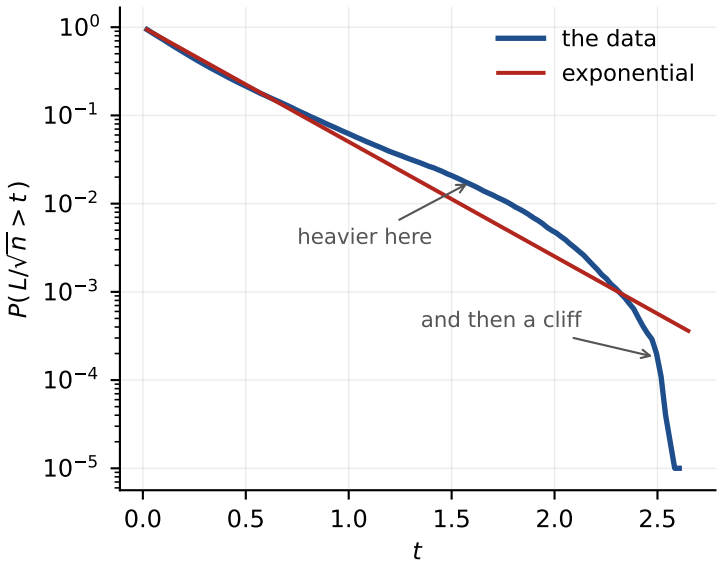
What distribution is $L(n)/\sqrt{n}$?

all 99,915 non-squares with n between 300,000 and 400,000

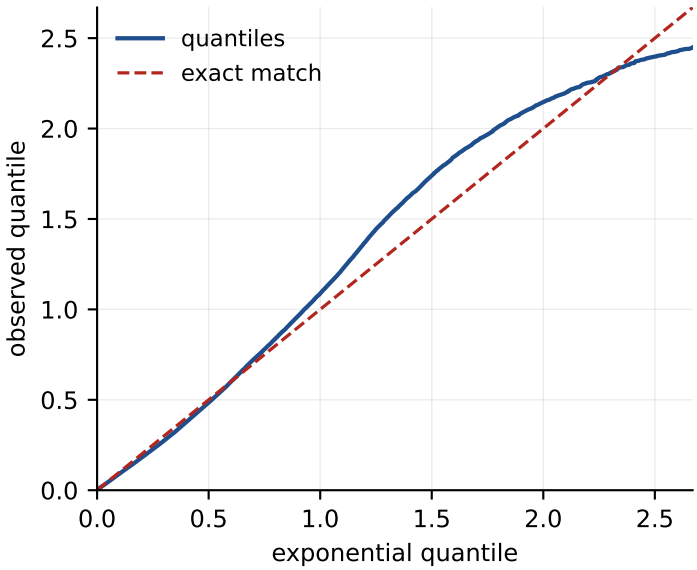
A. An exponential gets the shape almost exactly



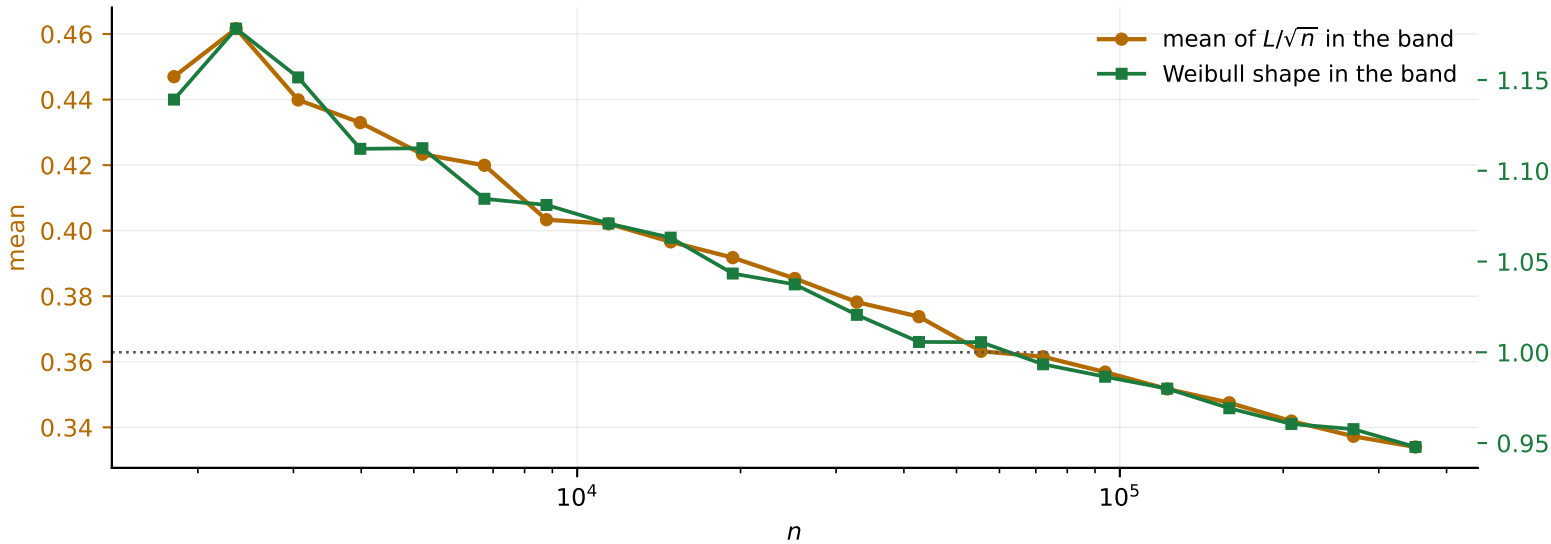
B. Survival: straight means exponential



C. Quantile plot against the exponential



D. The fit is good but the parameters drift, so no single distribution is right



Kolmogorov-Smirnov distance: exponential 0.0346, Weibull 0.0210.
At this sample size the 5% cut is 0.0043, so both are rejected. They are good descriptions and not true laws. The period is about the regulator divided by the Levy constant 1.187, and the spread comes from the class number.
