k against M: it falls, it decelerates, and it does not stop inside the data
straight line in log M (rms 0.0239)
$A + B/\log M$ $\to 0.555$ (rms 0.0043)
$A + BM^{-\beta}$, $\beta = 0.243$ $\to 0.863$ (rms 0.0026)
fitted $k(M)$
beyond the data
$k > 1$ hazard rising
$k = 1${,} exactly the exponential
$M \approx 163{,}435$
$k < 1$ hazard falling
The three curves agree on the data and disagree on the limit, from 0.56 to 0.86.
The measurement settles that k decelerates; it does not settle where it stops.
fitted Weibull shape k
M, the largest n for which $L(n)/\sqrt{n}$ is computed
